

### Adhesive tape

Flying splice in papermills, film-producing plants or the like is a common technique for replacing an old, almost fully unwound roll of paper by a new roll without having to stop the machines, with run at high speed. This is done using double-sided self-adhesive tapes, so-called tabs, which possess high adhesion and high tack. These tabs are bonded artistically in a zigzag form to the beginning of the web, a procedure requiring experienced personnel, with only about 4 – 5 minutes' time remaining for the entire procedure, owing to the high speed of the machines.

There are various products on the market, known as splicing tapes, for this “butt splicing” in flying splice, which are coated on both sides with pressure-sensitive adhesive composition. Adhesive tapes of this kind are marketed, inter alia, under the name tesafix (Beiersdorf).

The prior art describes diverse adhesive tapes for such purposes. For instance, EP 418 527 A2 discloses a method of preparing a reel of printing material in web form for automatic reel changers and an adhesive strip suitable for this purpose. DE 40 33 900 A1 also describes an adhesive tape suitable for a splice

The nonadhesive masking of otherwise exposed adhesive areas is taught by US 5,702,555 for more static loadings while securing a reel start, while DE 196 32 689 A2 discloses an adhesive tape of this kind for dynamic loading during the splicing method, the paper backing of this tape cleaving and masking the adhesive compositions with its residues.

In practice, even these adhesive tapes exhibit disadvantages, primarily because a splice does not succeed but instead ends as a break, without any evident reason for this.

It is an object of the invention to provide a remedy here.

In accordance with the invention, splices succeed without breaks, a preferred feature being the offset or distance V of the double-sided adhesive tape DO from the long edge LK of the adhesive tape.

- Tensile strength and elongation at break characteristics are much more readily controllable with film systems than in the case of paper backings. As

a result it is possible to splice even those carrier systems which are highly sensitive to tearing. The products may be adapted steplessly to the carrier systems that are to be spliced.

- Film systems exhibit no dimensional changes as a result of climatic conditions, and so the bales prepared for splicing can be stored for longer. Bale product spliced using paper systems must be supplied to the splicing operation immediately after preparation (dependent, of course, on the ambient climatic conditions).
- Film systems are better suited to mechanical processing (i.e., automatic attachment of the splice) owing to increased tensile strength and improved flatness.
- Coextruded polymeric composite systems may be produced in a defined manner in one operation, inexpensively and with few fluctuation parameters.

#### Cleaving systems

The cleavable system advantageously has a markedly lower cleavage resistance than the principal carrier (P1) which has to accommodate the tensile forces. A sufficient difference is helpful for the functional principle of the product of the invention.

Suitable cleaving systems include, for example, the following papers or paper composite systems or polymeric composite systems:

- Duplex papers: These papers are standard commercial products and are used, for example, in the production of filter materials and wallcoverings.
- Readily cleaving papers: The cleavage work is adjusted by way of the consolidation of the paper fiber structure. The lower the consolidation, the lower the cleavage work.  
Suitable paper types include, for example, machine-finished papers calendered on one side or else highly calendered kraft papers.
- Sized paper systems or sized film systems: The cleavage work is adjusted by way of the chemistry of the pressure-sensitive adhesive or of the coating system. The sizing or pressure-sensitive adhesive should have penetrated into the paper only to an insignificant extent.
- Coextruded polymeric composite systems: Extruded multilayer systems with low bond strength between the boundary layers.

- Clean cut edges are also helpful for the objectives of the present invention. During the cutting operation, no composition should be squeezed out. In particular, the cleavable attachment area of the cleaving material should not be covered by a pressure-sensitive adhesive composition.

Suitable cleaving paper comprises a variety of cleavable paper systems, such as

- Suitable self-adhesive compositions include all typical pressure-sensitive adhesive compositions, especially

- The splicing method, in this case the bonding operation using the splicing tape, may in particular take place in such a way that the adhesive tape is bonded to the running web at right angles (disadvantage: the cleavable system must cleave completely within fractions of seconds) but also at an acute angle (advantage: the process of cleavage runs as a wave through the adhesive tape), in particular up to 45°, especially up to 15°.

The drawing shows a diagram of an adhesive tape of the invention in cross section and is therefore intended to illustrate the invention by way of example. The reference symbols are explained in the claims.

### Test methods

Measuring the cleavage strength (internal bond strength) of papers or other composite systems

### **Purpose and scope of application**

Testing the strength of paper or other materials built up from fibers in the z direction, or composite systems. The cleavage strength is determined.

The cleavage strength is the force which has to be overcome in order to cleave a test element in the z direction.

### **Principle of the method**

Two adhesive tapes are applied to the system to be tested, located opposite each other, and are pulled apart at an angle of 180° in the tensile testing machine. The force to be overcome in order to cleave the system is the cleavage strength.

### **Instruments and atmospheric testing conditions**

Tensile testing machine

Blade or strip cutter 15 mm wide

Hand-held roller 2 kg

Atmospheric testing conditions: 23 +/- 1°C, 50 +/- 5% relative humidity

### **Materials**

Adhesive tape such as testband 7475

Width 20 mm, strips about 20 cm long

### **Test samples**

DIN A4 sheets

The samples must be conditioned for at least 16 hours under standard atmospheric conditions.

### **Test procedure**

Two adhesive tapes are placed on the system to be tested from both sides, located opposite each other, and are smoothed lightly with the finger in order to avoid air inclusions.

The bond is to be produced in such a way that, on one side, the ends of the adhesive tape project beyond the test element and, by being folded, can be stuck to each other to form a grip.

Using a steel rule, strips of a length of about 20 cm and 15 mm in width are cut centrally from the composite. The two grips of the projecting adhesive tape are then pulled apart by hand until cleavage of the test specimen can be detected.

In the case of very thin systems, care should be taken that the result is not falsified by the fact that the opposite edges of the adhesive tape have contact with the edge of the test element and stick to it.

The cleavage strength of the test element is specified in cN/cm.

## Application examples

The drawing describes the associated product construction.

The following coating base papers and polymer films were used for the splicing trials:

- [ A ] Coating base paper (grammage 134 g/m<sup>2</sup>, thickness 167  $\mu$ m)  
e.g.: Sappi Alfeld AG, 31061 Alfeld
- [ B ] MOPP film (grammage 45 g/m<sup>2</sup>, thickness 50  $\mu$ m)  
e.g.: Nowofol Kunststoffprodukte GmbH & Co KG, 83313 Siegsdorf
- [ C ] BOPP film Trespaphan GND 50 (grammage 44 g/m<sup>2</sup>, thickness 50  $\mu$ m)  
e.g.: Hoechst AG, Frankfurt

The following cleaving systems were used for the trial products:

- [ D ] Duplex filter paper  
Grammage 51 g/m<sup>2</sup>, thickness 90  $\mu$ m  
Cleavage work, transverse 34 - 44 cN/cm

- [ E ] Machine-finished paper calendered on one side  
Grammage 57 g/m<sup>2</sup>, thickness 74  $\mu$ m  
Cleavage work, transverse 33 - 38 cN/cm

- [ F ] Sized paper composite system with defined cleavage work.  
Two machine-calendered base papers are bonded together using a size containing starch. Grammage in each case 54 g/m<sup>2</sup>, thickness 66  $\mu$ m. The transverse cleavage work of the composite is 28 - 32 cN/cm.

- [ G ] Coextruded film composite system with defined cleavage work.  
A two-layer system is produced by coextrusion. The transverse cleavage work of the composite is 30 – 35 cN/cm.

The following backing sheets were used for the trial products:

- [ H ] BOPP film  
Grammage 44 g/m<sup>2</sup>, thickness 50  $\mu$ m, ultimate transverse tensile strength  $\geq 190$  N/ 15 mm
- [ I ] PET film  
Grammage 70 g/m<sup>2</sup>, thickness 50  $\mu$ m, ultimate transverse tensile strength 120 - 225 N/ 15 mm

- [ J ] Aluminized PET film

Grammage 35 g/m<sup>2</sup>, thickness 25  $\mu$ m, ultimate transverse tensile strength  
78 N/ 15 mm

- [ K ] Aluminum foil

Grammage 216 g/m<sup>2</sup>, thickness 80  $\mu$ m, ultimate transverse tensile strength  
72 - 135 N/ 15 mm
